Seamless Bidirectional Forwarding Detection (S-BFD)
draft-ietf-bfd-seamless-base-05

Abstract

This document defines a simplified mechanism to use Bidirectional Forwarding Detection (BFD) with large portions of negotiation aspects eliminated, thus providing benefits such as quick provisioning as well as improved control and flexibility to network nodes initiating the path monitoring.

This document updates RFC5880.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on December 21, 2015.

1. Introduction

Bidirectional Forwarding Detection (BFD), [RFC5880] and related documents, has efficiently generalized the failure detection mechanism for multiple protocols and applications. There are some improvements which can be made to better fit existing technologies. There is a possibility of evolving BFD to better fit new technologies. This document focuses on several aspects of BFD in order to further improve efficiency, to expand failure detection coverage and to allow BFD usage for wider scenarios. This document extends BFD to provide solutions to use cases listed in [I-D.ietf-bfd-seamless-use-case].

One key aspect of the mechanism described in this document eliminates the time between a network node wanting to perform a continuity test and completing the continuity test. In traditional BFD terms, the initial state changes from DOWN to UP are virtually nonexistent. Removal of this seam (i.e., time delay) in BFD provides applications a smooth and continuous operational experience. Therefore, "Seamless BFD" (S-BFD) has been chosen as the name for this mechanism.

2. Terminology

The reader is expected to be familiar with the BFD, IP and MPLS terminologies and protocol constructs. This section describes several new terminologies introduced by S-BFD.

- Classical BFD - BFD session types based on [RFC5880].
- S-BFD - Seamless BFD.
- S-BFD control packet - a BFD control packet for the S-BFD mechanism.
- S-BFD echo packet - a BFD echo packet for the S-BFD mechanism.
- S-BFD packet - a BFD control packet or a BFD echo packet.
- Entity - a function on a network node that S-BFD mechanism allows remote network nodes to perform continuity test to. An entity can be abstract (e.g., reachability) or specific (e.g., IP addresses, router-IDs, functions).
o SBFDInitiator - an S-BFD session on a network node that performs a continuity test to a remote entity by sending S-BFD packets.

o SBFDReflector - an S-BFD session on a network node that listens for incoming S-BFD control packets to local entities and generates response S-BFD control packets.

o Reflector BFD session - synonymous with SBFDReflector.

o S-BFD discriminator - a BFD discriminator allocated for a local entity and is being listened by an SBFDReflector.

o BFD discriminator - a BFD discriminator allocated for an SBFDInitiator.

o Initiator - a network node hosting an SBFDInitiator.

o Responder - a network node hosting an SBFDReflector.

Below figure describes the relationship between S-BFD terminologies.

```
+---------------------+                +------------------------+
|      Initiator      |                |         Responder      |
| +-----------------+ |                |    +-----------------+ |
| |  SBFDInitiator  |---S-BFD ctrl pkt----->|  SBFDReflector  | |
| | +-------------+ |<--S-BFD ctrl pkt------| +-------------+ | |
| | | BFD discrim | |                |    | |S-BFD discrim| | |
| | |             | |---S-BFD echo pkt---+  | |             | | |
| | +-------------+ | |                | |  | +----------^--+ | |
| +-----------------+<-------------------+  +------------|----+ |
|                     |                |                 |      |
|                     |                |             +---v----+ |
|                     |                |             | Entity | |
|                     |                |             +--------+ |
| +---------------------+                +------------------------+
```

Figure 1: S-BFD Terminology Relationship

3. Seamless BFD Overview

An S-BFD module on each network node allocates one or more S-BFD discriminators for local entities, and creates a reflector BFD session. Allocated S-BFD discriminators may be advertised by applications (e.g., OSPF/IS-IS). Required result is that applications, on other network nodes, possess the knowledge of the mapping from remote entities to S-BFD discriminators. The reflector BFD session is to, upon receiving an S-BFD control packet targeted to
one of local S-BFD discriminator values, transmit a response S-BFD control packet back to the initiator.

Once above setup is complete, any network nodes, having the knowledge of the mapping from a remote entity to an S-BFD discriminator, can quickly perform a continuity test to the remote entity by simply sending S-BFD control packets with corresponding S-BFD discriminator value in the "your discriminator" field.

For example:

```
<-------- IS-IS Network -------->

  +--------+
  |         |
  A--------B--------C--------D
  ^                             ^
  |                             |
  SystemID                      SystemID
  xxx                           yyy
  BFD Discrim                   BFD Discrim
  123                           456

Figure 2: S-BFD for IS-IS Network
```

The IS-IS with SystemID xxx (node A) allocates an S-BFD discriminator 123, and advertises the S-BFD discriminator 123 in an IS-IS TLV. The IS-IS with SystemID yyy (node D) allocates an S-BFD discriminator 456, and advertises the S-BFD discriminator 456 in an IS-IS TLV. A reflector BFD session is created on both network nodes (node A and node D). When network node A wants to check the reachability to network node D, node A can send an S-BFD control packet, destined to node D, with "your discriminator" field set to 456. When the reflector BFD session on node D receives this S-BFD control packet, then response S-BFD control packet is sent back to node A, which allows node A to complete the continuity test.

4. S-BFD Discriminators

4.1. S-BFD Discriminator Uniqueness

One important characteristics of an S-BFD discriminator is that it MUST be unique within an administrative domain. If multiple network nodes allocated a same S-BFD discriminator value, then S-BFD control packets falsely terminating on a wrong network node can result in a reflector BFD session to generate a response back, due to "your discriminator" matching. This is clearly not desirable. If only IP based S-BFD is considered, then it is possible for the reflector BFD
session to require demultiplexing of incoming S-BFD control packets with combination of destination IP address and "your discriminator". Then S-BFD discriminator only has to be unique within a local node. However, S-BFD is a generic mechanism defined to run on wide range of environments: IP, MPLS, etc. For other transports like MPLS, because of the need to use non-routable IP destination address, it is not possible for reflector BFD session to demultiplex using IP destination address. With PHP, there may not be any incoming label stack to aid in demultiplexing either. Thus, S-BFD imposes a requirement that S-BFD discriminators MUST be unique within an administrative domain.

4.2. Discriminator Pools

This subsection describes a discriminator pool implementation technique to minimize S-BFD discriminator collisions. The result will allow an implementation to better satisfy the S-BFD discriminator uniqueness requirement defined in Section 4.1.

- **SBFDInitiator** is to allocate a discriminator from the BFD discriminator pool. If the system also supports classical BFD that runs on [RFC5880], then the BFD discriminator pool SHOULD be shared by SBFDInitiator sessions and classical BFD sessions.

- **SBFDReflector** is to allocate a discriminator from the S-BFD discriminator pool. The S-BFD discriminator pool SHOULD be a separate pool than the BFD discriminator pool.

Remainder of this subsection describes the reasons for above suggestions.

Locally allocated S-BFD discriminator values for entities, listened by SBFDReflector sessions, may be arbitrary allocated or derived from values provided by applications. These values may be protocol IDs (e.g., System-ID, Router-ID) or network targets (e.g., IP address). To avoid derived S-BFD discriminator values already being assigned to other BFD sessions (i.e., SBFDInitiator sessions and classical BFD sessions), it is RECOMMENDED that discriminator pool for SBFDReflector sessions be separate from other BFD sessions.

Even when following the separate discriminator pool approach, collision is still possible between one S-BFD application to another S-BFD application, that may be using different values and algorithms to derive S-BFD discriminator values. If the two applications are using S-BFD for a same purpose (e.g., network reachability), then the colliding S-BFD discriminator value can be shared. If the two applications are using S-BFD for a different purpose, then the
collision must be addressed. How such collisions are addressed is outside the scope of this document.

5. Reflector BFD Session

Each network node creates one or more reflector BFD sessions. This reflector BFD session is a session which transmits S-BFD control packets in response to received S-BFD control packets with "your discriminator" having S-BFD discriminators allocated for local entities. Specifically, this reflector BFD session is to have following characteristics:

- MUST NOT transmit any S-BFD packets based on local timer expiry.
- MUST transmit an S-BFD control packet in response to a received S-BFD control packet having a valid S-BFD discriminator in the "your discriminator" field, unless prohibited by local policies (e.g., administrative, security, rate-limiter, etc).
- MUST be capable of sending only two states: UP and ADMINDOWN.

One reflector BFD session may be responsible for handling received S-BFD control packets targeted to all locally allocated S-BFD discriminators, or few reflector BFD sessions may each be responsible for subset of locally allocated S-BFD discriminators. This policy is a local matter, and is outside the scope of this document.

Note that incoming S-BFD control packets may be IPv4, IPv6 or MPLS based. How such S-BFD control packets reach an appropriate reflector BFD session is also a local matter, and is outside the scope of this document.

6. State Variables

S-BFD introduces new state variables, and modifies the usage of existing ones.

6.1. New State Variables

A new state variable is added to the base specification in support of S-BFD.

- bfd.SessionType: This is a variable introduced by [I-D.ietf-bfd-multipoint] and describes the type of this session. Allowable values for S-BFD sessions are:
**SBFDInitiator** - an S-BFD session on a network node that performs a continuity test to a target entity by sending S-BFD packets.

**SBFDReflector** - an S-BFD session on a network node that listens for incoming S-BFD control packets to local entities and generates response S-BFD control packets.

The `bfd.SessionType` variable MUST be initialized to the appropriate type when an S-BFD session is created.

### 6.2. State Variable Initialization and Maintenance

Some state variables defined in section 6.8.1 of the BFD base specification need to be initialized or manipulated differently depending on the session type.

- `bfd.DemandMode`: This variable MUST be initialized to 1 for session type SBFDInitiator, and MUST be initialized to 0 for session type SBFDReflector.

### 7. S-BFD Procedures

#### 7.1. Demultiplexing of S-BFD Control Packet

S-BFD packet MUST be demultiplexed with lower layer information (e.g., dedicated destination UDP port, associated channel type). Following procedure SHOULD be executed on both initiator and reflector.

If S-BFD packet

If S-BFD packet is for SBFDReflector

Packet MUST be looked up to locate a corresponding SBFDReflector session based on the value from the "your discriminator" field in the table describing S-BFD discriminators.

Else

Packet MUST be looked up to locate a corresponding SBFDInitiator session or classical BFD session based on the value from the "your discriminator" field in the table describing BFD discriminators.

If session is SBFDInitiator
Destination of the packet (i.e., destination IP address) SHOULD be validated to be for self.

Else

Packet MUST be discarded

Else

Procedure described in [RFC5880] MUST be applied.

More details on S-BFD control packet demultiplexing are described in relevant S-BFD data plane documents.

7.2.  Initiator Procedures

S-BFD control packets transmitted by an SBFDInitiator MUST set "your discriminator" field to an S-BFD discriminator corresponding to the remote entity.

Every SBFDInitiator MUST have a locally unique "my discriminator" allocated from the BFD discriminator pool.

Below ASCII art describes high level concept of continuity test using S-BFD. R2 allocates XX as the S-BFD discriminator for its network reachability purpose, and advertises XX to neighbors. ASCII art shows R1 and R4 performing a continuity test to R2.

```
+--- md=50/yd=XX (ping) ----+
    |                         |
    | +-- md=XX/yd=50 (pong) --+ |
    |                          | |
    | v                        | v
R1 ==================== R2 [*] ========= R3 ========= R4
    | ^                        |^ |
    | +-- md=60/yd=XX (ping) --+|
    |                         |
    | v                        | |
    | +-- md=XX/yd=60 (pong) ---+|

[*] Reflector BFD session on R2.
=== Links connecting network nodes.
--- S-BFD control packet traversal.
```

Figure 3: S-BFD Continuity Test
7.2.1. SBFDInitiator State Machine

An SBFDInitiator may be a persistent session on the initiator with a timer for S-BFD control packet transmissions (stateful SBFDInitiator). An SBFDInitiator may also be a module, a script or a tool on the initiator that transmits one or more S-BFD control packets "when needed" (stateless SBFDInitiator). For stateless SBFDInitiators, a complete BFD state machine may not be applicable. For stateful SBFDInitiators, the states and the state machine described in [RFC5880] will not function due to SBFDReflector session only sending UP and ADMINDOWN states (i.e., SBFDReflector session does not send INIT state). The following diagram provides the RECOMMENDED state machine for stateful SBFDInitiators. The notation on each arc represents the state of the SBFDInitiator (as received in the State field in the S-BFD control packet) or indicates the expiration of the Detection Timer.

```
+--+-+  
|   |  |
| ADMIN DOWN, TIMER |
|               V 
----+  UP +------+
| DOWN |--------------------| UP |----+
|      |<--------------------|  UP |<---+
+------+
```

Figure 4: SBFDInitiator FSM

Note that the above state machine is different from the base BFD specification[RFC5880]. This is because the INIT state is no longer applicable for the SBFDInitiator. Another important difference is the transition of the state machine from the DOWN state to the UP state when a packet with State UP is received by the SBFDInitiator. The definitions of the states and the events have the same meaning as in the base BFD specification [RFC5880].

7.2.2. Transmission of S-BFD Control Packet by SBFDInitiator

Contents of S-BFD control packets sent by an SBFDInitiator MUST be set as follows:

Version

Set to the current version number (1).

Diagnostic (Diag)
MAY be set to appropriate value for communicating with peer.

State (Sta)

Set to the value indicated by local state.

Poll (P)

Set to 1 if the local system is sending a Poll Sequence.

Final (F)

Set to 1 if the local system is responding to a Control packet received with the Poll (P) bit set, or 0 if not.

Control Plane Independent (C)

Set to 1 if the local system’s BFD implementation is independent of the control plane (it can continue to function through a disruption of the control plane.)

Authentication Present (A)

Set to 1 if authentication is in use on this session (bfd.AuthType is nonzero), or 0 if not.

Demand (D)

MUST be set always.

Multipoint (M)

MUST be set to 0.

Detect Mult

MUST be set to a value describing locally used multiplier value.

Length

Set to the appropriate length, based on the fixed header length (24) plus any Authentication Section.

My Discriminator

Set to value assigned by local node.
Your Discriminator

Set to value corresponding to remote entity.

Desired Min TX Interval

MUST be set to a value describing local desired minimum transmit interval.

Required Min RX Interval

MUST be set to 0.

Required Min Echo RX Interval

MUST be set to 0.

7.3. Responder Procedures

A network node which receives S-BFD control packets transmitted by an initiator is referred as responder. The responder, upon reception of S-BFD control packets, is to perform necessary relevant validations described in [RFC5880], [RFC5881], [RFC5883], [RFC5884] and [RFC5885].

7.3.1. Responder Demultiplexing

S-BFD packet MUST be demultiplexed with lower layer information (e.g., dedicated destination UDP port, associated channel type). Following procedure SHOULD be executed by responder:

If "your discriminator" not one of the entry allocated for local entities

Packet MUST NOT be considered for this mechanism.

Else

Packet is determined to be handled by a reflector BFD session responsible for that S-BFD discriminator.

If local policy allows (e.g., administrative, security, rate-limiter, etc)

Chosen reflector BFD session SHOULD transmit a response BFD control packet using procedures described in Section 7.3.2.
7.3.2. Transmission of S-BFD Control Packet by SBFDReflector

Contents of S-BFD control packets sent by an SBFDReflector MUST be set as follows:

Version

Set to the current version number (1).

Diagnostic (Diag)

MAY be set to appropriate value for communicating with peer.

State (Sta)

MUST be set to UP or ADMINDOWN. Clarification of reflector BFD session state is described in Section 7.8.

Poll (P)

Set to 1 if the local system is sending a Poll Sequence, or 0 if not.

Final (F)

Set to 1 if the local system is responding to a Control packet received with the Poll (P) bit set, or 0 if not.

Control Plane Independent (C)

Set to 1 if the local system’s BFD implementation is independent of the control plane (it can continue to function through a disruption of the control plane.)

Authentication Present (A)

Set to 1 if authentication is in use on this session (bfd.AuthType is nonzero), or 0 if not.

Demand (D)

MUST be cleared.

Multipoint (M)

MUST be set to 0.

Detect Mult
MUST be copied from received "Detection Multiplier".

Length

Set to the appropriate length, based on the fixed header length (24) plus any Authentication Section.

My Discriminator

MUST be copied from received "your discriminator".

Your Discriminator

MUST be copied from received "my discriminator".

Desired Min TX Interval

MUST be copied from received "Desired Min TX Interval".

Required Min RX Interval

MUST be set to a value describing how many incoming control packets this reflector BFD session can handle. Further details are described in Section 7.8.

Required Min Echo RX Interval

If device supports looping back S-BFD echo packets

MUST set non-zero value desired by local device.

Else

MUST be set to 0.

7.4. Diagnostic Values

Diagnostic value in both directions MAY be set to a certain value, to attempt to communicate further information to both ends. However, details of such are outside the scope of this specification.

7.5. The Poll Sequence

Poll sequence MAY be used in both directions. The Poll sequence MUST operate in accordance with [RFC5880]. An SBFDReflector MAY use the Poll sequence to slow down that rate at which S-BFD control packets are generated from an SBFDInitiator. This is done by the SBFDReflector using procedures described in Section 7.8 and setting
the Poll (P) bit in the reflected S-BFD control packet. The SBFDInitiator is to then send the next S-BFD control packet with the Final (F) bit set. If an SBFDReflector receives an S-BFD control packet with Poll (P) bit set, then the SBFDReflector MUST respond with an S-BFD control packet with Poll (P) bit cleared and Final (F) bit set.

7.6. Control Plane Independent (C)

Control plane independent (C) bit for an SBFDInitiator sending S-BFD control packets to a reflector BFD session MUST work according to [RFC5880]. Reflector BFD session also MUST work according to [RFC5880]. Specifically, if reflector BFD session implementation does not share fate with control plane, then response S-BFD control packets transmitted MUST have control plane independent (C) bit set. If reflector BFD session implementation shares fate with control plane, then response S-BFD control packets transmitted MUST NOT have control plane independent (C) bit set.

7.7. Additional SBFDInitiator Behaviors

- If the SBFDInitiator receives a valid S-BFD control packet in response to transmitted S-BFD control packet to a remote entity, then the SBFDInitiator SHOULD conclude that S-BFD control packet reached the intended remote entity.

- When a sufficient number of S-BFD packets have not arrived as they should, the SBFDInitiator SHOULD declare loss of reachability to the remote entity. The criteria for declaring loss of reachability and the action that would be triggered as a result are outside the scope of this document.

- Relating to above bullet item, it is critical for an implementation to understand the latency to/from the reflector BFD session on the responder. In other words, for very first S-BFD packet transmitted by the SBFDInitiator, an implementation MUST NOT expect response S-BFD packet to be received for time equivalent to sum of latencies: initiator to responder and responder back to initiator.

- If the SBFDInitiator receives an S-BFD control packet with Demand (D) bit set, the packet MUST be discarded.

7.8. Additional SBFDReflector Behaviors

- S-BFD control packets transmitted by the SBFDReflector MUST have "Required Min RX Interval" set to a value which expresses how many incoming S-BFD control packets this SBFDReflector can handle. The
SBFDReflector can control how fast SBFIInitiators will be sending S-BFD control packets to self by ensuring "Required Min RX Interval" indicates a value based on the current load.

- If the SBFDReflector wishes to communicate to some or all SBFIInitiators that monitored local entity is "temporarily out of service", then S-BFD control packets with "state" set to ADMINDOWN are sent to those SBFIInitiators. The SBFIInitiators, upon reception of such packets, MUST NOT conclude loss of reachability to corresponding remote entity, and MUST back off packet transmission interval for the remote entity to an interval no faster than 1 second. If the SBFDReflector is generating a response S-BFD control packet for a local entity that is in service, then "state" in response BFD control packets MUST be set to UP.

- If an SBFDReflector receives an S-BFD control packet with Demand (D) bit cleared, the packet MUST be discarded.

8. Scaling Aspect

This mechanism brings forth one noticeable difference in terms of scaling aspect: number of SBFDReflector. This specification eliminates the need for egress nodes to have fully active BFD sessions when only one side desires to perform continuity tests. With introduction of reflector BFD concept, egress no longer is required to create any active BFD session per path/LSP/function basis. Due to this, total number of BFD sessions in a network is reduced.

9. Co-existence with Classical BFD Sessions

Initial packet demultiplexing requirement is described in Section 7.1. Because of this, S-BFD mechanism can co-exist with classical BFD sessions.

10. S-BFD Echo Function

The concept of the S-BFD Echo function is similar to the BFD Echo function described in [RFC5880]. S-BFD echo packets have the destination of self, thus S-BFD echo packets are self-generated and self-terminated after traversing a link/path. S-BFD echo packets are expected to u-turn on the target node in the data plane and MUST NOT be processed by any reflector BFD sessions on the target node.

When using the S-BFD Echo function, it is RECOMMENDED that:

- Both S-BFD control packets and S-BFD echo packets be sent.
Both S-BFD control packets and S-BFD echo packets have the same semantics in the forward direction to reach the target node. In other words, it is not preferable to send just S-BFD echo packets without also sending S-BFD control packets. There are two reasons behind this suggestion:

- S-BFD control packets can verify the reachability to intended target node, which allows one to have confidence that S-BFD echo packets are u-turning on the expected target node.
- S-BFD control packets can detect when the target node is going out of service (i.e., via receiving back ADMINDOWN state).

The usage of the "Required Min Echo RX Interval" field is described in Section 7.2.2 and Section 7.3.2. Because of the stateless nature of SBFDReflector sessions, a value specified the "Required Min Echo RX Interval" field in both directions is not very meaningful. Thus it is RECOMMENDED that the "Required Min Echo RX Interval" field simply be set to zero in both directions.

Following aspects of S-BFD Echo functions are left as implementation details, and are outside the scope of this document:

- Format of the S-BFD echo packet (e.g., data beyond UDP header).
- Procedures on when and how to use the S-BFD Echo function.

11. Security Considerations

Same security considerations as [RFC5880], [RFC5881], [RFC5883], [RFC5884] and [RFC5885] apply to this document. Additionally, implementing the following measures will strengthen security aspects of the mechanism described by this document:

- SBFDInitiator MAY pick crypto sequence number based on authentication mode configured.
- SBFDReflector MUST NOT look at the crypto sequence number before accepting the packet.
- SBFDReflector MAY look at the Key ID [I-D.ietf-bfd-generic-crypto-auth] in the incoming packet and verify the authentication data.
- SBFDReflector MUST accept the packet if authentication is successful.
o SBFDReflector MUST compute the Authentication data and MUST use the same sequence number that it received in the S-BFD control packet that it is responding to.

o SBFDInitiator MUST accept the S-BFD control packet if it either comes with the same sequence number as it had sent or it’s within the window that it finds acceptable (described in detail in [I-D.ietf-bfd-generic-crypto-auth])

Using the above method,

o SBFDReflector continue to remain stateless despite using security.

o SBFDReflector are not susceptible to replay attacks as they always respond to S-BFD control packets irrespective of the sequence number carried.

o An attacker cannot impersonate the responder since the SBFDInitiator will only accept S-BFD control packets that come with the sequence number that it had originally used when sending the S-BFD control packet.

12. IANA Considerations

No action is required by IANA for this document.

15.1. Normative References

15.2. Informative References

Consider a scenario where we have two nodes and both are S-BFD capable.

Node A (IP 192.0.2.1) ----------------- Node B (IP 192.0.2.2)

Man in the Middle (MiM)

Assume node A reserved a discriminator 0x01010101 for target identifier 192.0.2.1 and has a reflector session in listening mode. Similarly node B reserved a discriminator 0x02020202 for its target identifier 192.0.2.2 and also has a reflector session in listening mode.

Suppose MiM sends a spoofed packet with MyDisc = 0x01010101, YourDisc = 0x02020202, source IP as 192.0.2.1 and dest IP as 192.0.2.2. When this packet reaches Node B, the reflector session on Node B will swap the discriminators and IP addresses of the received packet and reflect it back, since YourDisc of the received packet matched with reserved discriminator of Node B. The reflected packet that reached Node A will have MyDisc=0x02020202 and YourDisc=0x01010101. Since YourDisc of the received packet matched the reserved discriminator of Node A, Node A will swap the discriminators and reflects the packet back to Node B. Since reflectors MUST set the TTL of the reflected packets to 255, the above scenario will result in an infinite loop with just one malicious packet injected from MiM.

FYI: Packet fields do not carry any direction information, i.e., if this is Ping packet or reply packet.

Solutions

The current proposals to avoid the loop problem are:

- Overload "D" bit (Demand mode bit): Initiator always sets the ‘D’ bit and reflector clears it. This way we can identify if a received packet was a reflected packet and avoid reflecting it back. However this changes the interpretation of ‘D’ bit.

- Use of State field in the BFD control packets: Initiator will always send packets with State set to DOWN and reflector will send back packets with state field set to UP. Reflectors will never
reflect any received packets with state as UP. However the only
issue is the use of state field differently i.e., state in the
S-BFD control packet from initiator does not reflect the local
state which is anyway not significant at reflector.

- Use of local discriminator as My Disc at reflector: Reflector will
  always fill in My Discriminator with a locally allocated
discriminator value (not reserved discriminators) and will not
  copy it from the received packet.
