Abstract

CUBIC is an extension to the current TCP standards. The protocol differs from the current TCP standards only in the congestion window adjustment function in the sender side. In particular, it uses a cubic function instead of a linear window increase function of the current TCP standards to improve scalability and stability under fast and long distance networks. CUBIC and its predecessor algorithm have been adopted as default by Linux and have been used for many years. This document provides a specification of CUBIC to enable third party implementation and to solicit the community feedback through experimentation on the performance of CUBIC.

1. Introduction

The low utilization problem of TCP in fast long-distance networks is well documented in [K03][RFC3649]. This problem arises from a slow increase of congestion window following a congestion event in a network with a large bandwidth delay product (BDP). Our experience [HKLRX06] indicates that this problem is frequently observed even in the range of congestion window sizes over several hundreds of packets (each packet is sized around 1000 bytes) especially under a network path with over 100ms round-trip times (RTTs). This problem is equally applicable to all Reno style TCP standards and their variants, including TCP-RENO [RFC5681], TCP-NewReno [RFC6582][RFC6675], SCTP [RFC4960], TFRC [RFC5348] that use the same linear increase function for window growth, which we refer to collectively as Standard TCP below.

CUBIC [HRX08] is a modification to the congestion control mechanism of Standard TCP, in particular, to the window increase function of Standard TCP senders, to remedy this problem. Specifically, it uses a cubic function instead of a linear window increase function of the Standard TCP to improve scalability and stability under fast and long distance networks.

BIC-TCP, a predecessor of CUBIC, has been selected as default TCP congestion control algorithm by Linux in the year 2005 and been used for several years by the Internet community at large. CUBIC uses a similar window growth function as BIC-TCP and is designed to be less aggressive and fairer to TCP in bandwidth usage than BIC-TCP while maintaining the strengths of BIC-TCP such as stability, window scalability and RTT fairness. CUBIC has already been deployed globally by Linux. Through extensive testing in various Internet scenarios, we believe that CUBIC is safe for testing and deployment in the global Internet.

In the ensuing sections, we first brefly explain the design principle of CUBIC, then provide the exact specification of CUBIC, and finally discuss the safety features of CUBIC following the guidelines specified in [RFC5033].

2. Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].
3. Design principle of CUBIC

CUBIC [HRX08] uses a cubic window increase function in terms of the elapsed time from the last congestion event. While most alternative algorithms to Standard TCP uses a convex increase function where during congestion avoidance the window increment is always increasing, CUBIC uses both the concave and convex profiles of a cubic function for window increase. After a window reduction following a loss event detected by duplicate ACKs, it registers the window size where it got the loss event as $W_{\text{max}}$ and performs a multiplicative decrease of congestion window and the regular fast recovery and retransmit of Standard TCP. After it enters into congestion avoidance from fast recovery, it starts to increase the window using the concave profile of the cubic function. The cubic function is set to have its plateau at $W_{\text{max}}$ so the concave growth continues until the window size becomes $W_{\text{max}}$. After that, the cubic function turns into a convex profile and the convex window growth begins. This style of window adjustment (concave and then convex) improves protocol and network stability while maintaining high network utilization [CEHRX07]. This is because the window size remains almost constant, forming a plateau around $W_{\text{max}}$ where network utilization is deemed highest and under steady state, most window size samples of CUBIC are close to $W_{\text{max}}$, thus promoting high network utilization and protocol stability. Note that protocols with convex increase functions have the maximum increments around $W_{\text{max}}$ and introduces a large number of packet bursts around the saturation point of the network, likely causing frequent global loss synchronizations.

Another notable feature of CUBIC is that its window increase rate is mostly independent of RTT, and follows a (cubic) function of the elapsed time from the beginning of congestion avoidance. This feature promotes per-flow fairness to Standard TCP as well as RTT-fairness. Note that Standard TCP performs well under short RTT and small bandwidth (or small BDP) networks. Only in a large long RTT and large bandwidth (or large BDP) networks, it has the scalability problem. An alternative protocol to Standard TCP designed to be friendly to Standard TCP at a per-flow basis must operate to increase its window much less aggressively in small BDP networks than in large BDP networks. In CUBIC, its window growth rate is slowest around the inflection point of the cubic function and this function does not depend on RTT. In a smaller BDP network where Standard TCP flows are working well, the absolute amount of the window decrease at a loss event is always smaller because of the multiplicative decrease. Therefore, in CUBIC, the starting window size after a loss event from which the window starts to increase, is smaller in a smaller BDP network, thus falling nearer to the plateau of the cubic function where the growth rate is slowest. By setting appropriate values of
the cubic function parameters, CUBIC sets its growth rate always no faster than Standard TCP around its inflection point. When the cubic function grows slower than the window of Standard TCP, CUBIC simply follows the window size of Standard TCP to ensure fairness to Standard TCP in a small BDP network. We call this region where CUBIC behaves like Standard TCP, the TCP-friendly region.

CUBIC maintains the same window growth rate independent of RTTs outside of the TCP-friendly region, and flows with different RTTs have the similar window sizes under steady state when they operate outside the TCP-friendly region. This ensures CUBIC flows with different RTTs to have their bandwidth shares (approximately, window/RTT) linearly proportional to the inverse of their RTT ratio (the longer RTT, the smaller the share). This behavior is the same as that of Standard TCP under high statistical multiplexing environments where packet losses are independent of individual flow rates. However, under low statistical multiplexing environments, the bandwidth share ratio of Standard TCP flows with different RTTs is squarely proportional to the inverse of their RTT ratio [XHR04]. CUBIC always ensures the linear ratio independent of the levels of statistical multiplexing. This is an improvement over Standard TCP. While there is no consensus on a particular bandwidth share ratios of different RTT flows, we believe that under wired Internet, use of the linear share notion seems more reasonable than equal share or a higher order shares. HTCP [LS08] currently uses the equal share.

CUBIC sets the multiplicative window decrease factor to 0.7 while Standard TCP uses 0.5. While this improves the scalability of the protocol, a side effect of this decision is slower convergence especially under low statistical multiplexing environments. This design choice is following the observation that the author of HSTCP [RFC3649] has made along with other researchers (e.g., [GV02]): the current Internet becomes more asynchronous with less frequent loss synchronizations with high statistical multiplexing. Under this environment, even strict Multiplicative-Increase Multiplicative-Decrease (MIMD) can converge. CUBIC flows with the same RTT always converge to the same share of bandwidth independent of statistical multiplexing, thus achieving intra-protocol fairness. We also find that under the environments with sufficient statistical multiplexing, the convergence speed of CUBIC flows is reasonable.

4. CUBIC Congestion Control

The unit of all window sizes in this document is segments of the maximum segment size (MSS), and the unit of all times is seconds.
4.1. Window growth function

CUBIC maintains the acknowledgment (ACK) clocking of Standard TCP by increasing congestion window only at the reception of ACK. The protocol does not make any change to the fast recovery and retransmit of TCP, such as TCP-NewReno [RFC6582] [RFC6675]. During congestion avoidance after fast recovery, CUBIC changes the window update algorithm of Standard TCP. Suppose that $W_{\text{max}}$ is the window size before the window is reduced in the last fast retransmit and recovery.

The window growth function of CUBIC uses the following function:

$$W_{\text{cubic}}(t) = C*(t-K)^3 + W_{\text{max}} \quad \text{(Eq. 1)}$$

where $C$ is a constant fixed to determine the aggressiveness of window growth in high BDP networks, $t$ is the elapsed time from the last window reduction that is measured right after the fast recovery in response to duplicate ACKs or after the congestion window reduction in response to ECN-Echo ACKs, and $K$ is the time period that the above function takes to increase the current window size to $W_{\text{max}}$ if there is no further loss event and is calculated by using the following equation:

$$K = \text{cubic_root}(W_{\text{max}}*(1-\beta_{\text{cubic}})/C) \quad \text{(Eq. 2)}$$

where $\beta_{\text{cubic}}$ is the CUBIC multiplication decrease factor, that is, when a packet loss detected by duplicate ACKs or a network congestion detected by ECN-Echo ACKs occurs, CUBIC reduces its current window cwnd to $W_{\text{cubic}}(0)=W_{\text{max}}*\beta_{\text{cubic}}$. We discuss how we set $\beta_{\text{cubic}}$ in Section 4.5 and how we set $C$ in Section 5.

Upon receiving an ACK during congestion avoidance, CUBIC computes the window growth rate during the next RTT period using Eq. 1. It sets $W_{\text{cubic}}(t+\text{RTT})$ as the candidate target value of congestion window, where RTT is the weighted average RTT calculated by the standard TCP.

Depending on the value of the current window size cwnd, CUBIC runs in three different modes. First, if cwnd is less than the window size that Standard TCP would reach at time $t$ after the last loss event, then CUBIC is in the TCP friendly region (we describe below how to determine this window size of Standard TCP in term of time $t$). Otherwise, if cwnd is less than $W_{\text{max}}$, then CUBIC is the concave region, and if cwnd is larger than $W_{\text{max}}$, CUBIC is in the convex region. Below, we describe the exact actions taken by CUBIC in each region.
4.2. TCP-friendly region

Standard TCP performs well in certain types of networks, for example, under short RTT and small bandwidth (or small BDP) networks. In these networks, we use the TCP-friendly region to ensure that CUBIC achieves at least the same throughput as the standard TCP.

When receiving an ACK in congestion avoidance, we first check whether the protocol is in the TCP region or not. This is done by estimating the average rate of the Standard TCP using a simple analysis described in [FHP00]. It considers the Standard TCP as a special case of an Additive Increase and Multiplicative Decrease algorithm (AIMD), which has an additive factor $\alpha_{\text{aimd}}$ and a multiplicative factor $\beta_{\text{aimd}}$ with the following function:

$$\text{AVG}_W_{\text{aimd}} = \frac{\alpha_{\text{aimd}} \cdot (1 + \beta_{\text{aimd}})}{2 \cdot (1 - \beta_{\text{aimd}}) \cdot p} \right)^{0.5} \text{ (Eq. 3)}$$

By the same analysis, the average window size of Standard TCP is $(1.5/p)^{0.5}$, as the Standard TCP is a special case of AIMD with $\alpha_{\text{aimd}}=1$ and $\beta_{\text{aimd}}=0.5$. Thus, for Eq. 3 to be the same as that of Standard TCP, $\alpha_{\text{aimd}}$ must be equal to $3 \cdot (1 - \beta_{\text{aimd}})/(1 + \beta_{\text{aimd}})$. As AIMD increases its window by $\alpha_{\text{aimd}}$ per RTT, we can get the window size of AIMD in terms of the elapsed time $t$ as follows:

$$W_{\text{aimd}}(t) = W_{\text{max}} \cdot \beta_{\text{aimd}} + \left[3 \cdot (1 - \beta_{\text{aimd}})/(1 + \beta_{\text{aimd}})\right] \cdot (t/RTT) \text{ (Eq. 4)}$$

If $W_{\text{cubic}}(t)$ is less than $W_{\text{aimd}}(t)$ (it does not matter whether $cwnd$ is greater than or less than $W_{\text{max}}$), then the protocol is in the TCP friendly region and $cwnd$ SHOULD be set to $W_{\text{aimd}}(t)$ at each reception of ACK.

4.3. Concave region

When receiving an ACK in congestion avoidance, if the protocol is not in the TCP-friendly region and $cwnd$ is less than $W_{\text{max}}$, then the protocol is in the concave region. In this region, $cwnd$ MUST be incremented by $(W_{\text{cubic}}(t+RTT) - cwnd)/cwnd$ for each received ACK, where $W_{\text{cubic}}(t+RTT)$ is calculated using Eq. 1.

4.4. Convex region

When the current window size of CUBIC is larger than $W_{\text{max}}$, it passes the plateau of the cubic function after which CUBIC follows the convex profile of the cubic function. Since $cwnd$ is larger than the previous saturation point $W_{\text{max}}$, this indicates that the network
conditions might have been perturbed since the last loss event, possibly implying more available bandwidth after some flow departures. Since the Internet is highly asynchronous, some amount of perturbation is always possible without causing a major change in available bandwidth. In this phase, CUBIC is being very careful by very slowly increasing its window size. The convex profile ensures that the window increases very slowly at the beginning and gradually increases its growth rate. We also call this phase as the maximum probing phase since CUBIC is searching for a new $W_{\text{max}}$. In this region, $cwnd$ MUST be incremented by $(W_{\text{cubic}}(t+RTT) - cwnd)/cwnd$ for each received ACK, where $W_{\text{cubic}}(t+RTT)$ is calculated using Eq. 1.

4.5. Multiplicative decrease

When a packet loss detected by duplicate ACKs or a network congestion detected by ECN-Echo ACKs occurs, CUBIC updates its $W_{\text{max}}$, $cwnd$, and $ssthresh$ (slow start threshold) as follows. Parameter $\beta_{\text{cubic}}$ SHOULD be set to 0.7.

\[
\frac{W_{\text{max}} = cwnd;}{\text{// save window size before reduction}} \\
\frac{ssthresh = cwnd \times \beta_{\text{cubic}};}{\text{// new slow start threshold}} \\
\frac{cwnd = cwnd \times \beta_{\text{cubic}};}{\text{// window reduction}}
\]

A side effect of setting $\beta_{\text{cubic}}$ to a bigger value than 0.5 is slower convergence. We believe that while a more adaptive setting of $\beta_{\text{cubic}}$ could result in faster convergence, it will make the analysis of the protocol much harder. This adaptive adjustment of $\beta_{\text{cubic}}$ is an item for the next version of CUBIC.

4.6. Fast convergence

To improve the convergence speed of CUBIC, we add a heuristic in the protocol. When a new flow joins the network, existing flows in the network need to give up their bandwidth shares to allow the flow some room for growth if the existing flows have been using all the bandwidth of the network. To increase this release of bandwidth by existing flows, the following mechanism called fast convergence SHOULD be implemented.

With fast convergence, when a loss event occurs, before a window reduction of congestion window, a flow remembers the last value of $W_{\text{max}}$ before it updates $W_{\text{max}}$ for the current loss event. Let us call the last value of $W_{\text{max}}$ to be $W_{\text{last max}}$. 

if (W_max < W_last_max) { // should we make room for others
    W_last_max = W_max;             // remember the last W_max
    W_max = W_max*(1.0+beta_cubic)/2.0; // further reduce W_max
} else {
    W_last_max = W_max              // remember the last W_max
}

At a loss event, if the current value of W_max is less than W_last_max, this indicates that the saturation point experienced by this flow is getting reduced because of the change in available bandwidth. Then we allow this flow to release more bandwidth by reducing W_max further. This action effectively lengthens the time for this flow to increase its window because the reduced W_max forces the flow to have the plateau earlier. This allows more time for the new flow to catch up its window size.

The fast convergence is designed for network environments with multiple CUBIC flows. In network environments with only a single CUBIC flow and without any other traffic, the fast convergence SHOULD be disabled.

4.7. Timeout

In case of timeout, CUBIC follows the standard TCP to reduce cwnd, but sets ssthresh using beta_cubic (same as in Section 4.5).

4.8. Slowstart

CUBIC MUST employ a slow start algorithm, when the cwnd is no more than ssthresh. Among the slow start algorithms, CUBIC MAY choose the standard TCP slow start [RFC5681] in general networks, or the limited slow start [RFC3742] or hybrid slow start [HR08] for high-bandwidth and long-distance networks.

5. Discussion

In this section, we further discuss the safety features of CUBIC following the guidelines specified in [RFC5033].

With a deterministic loss model where the number of packets between two successive lost events is always 1/p, CUBIC always operates with the concave window profile which greatly simplifies the performance analysis of CUBIC. The average window size of CUBIC can be obtained by the following function:

\[
\text{AVG}_W_{\text{cubic}} = \frac{C(3+\text{beta}_\text{cubic})}{4(1-\text{beta}_\text{cubic})}\frac{\text{RTT}^{0.75}}{p^{0.75}} \quad (\text{Eq. 5})
\]
With beta_cubic set to 0.7, the above formula is reduced to:

\[ \text{AVG}_W_{\text{cubic}} = (C \times 3.7 / 1.2)^{0.25} \times (\text{RTT}^{0.75}) / (p^{0.75}) \]  
(Eq. 6)

We will determine the value of C in the following subsection using Eq. 6.

5.1.  Fairness to standard TCP

In environments where standard TCP is able to make reasonable use of the available bandwidth, CUBIC does not significantly change this state.

Standard TCP performs well in the following two types of networks:

1. networks with a small bandwidth-delay product (BDP)

2. networks with a short RTT, but not necessarily a small BDP

CUBIC is designed to behave very similarly to standard TCP in the above two types of networks. The following two tables show the average window size of standard TCP, HSTCP, and CUBIC. The average window size of standard TCP and HSTCP is from [RFC3649]. The average window size of CUBIC is calculated by using Eq. 6 and CUBIC TCP friendly mode for three different values of C.

Response function of standard TCP, HSTCP, and CUBIC in networks with RTT = 0.01 seconds. The average window size is in MSS-sized segments.

Both tables show that CUBIC with any of these three C values is more friendly to TCP than HSTCP, especially in networks with a short RTT where TCP performs reasonably well. For example, in a network with RTT = 0.01 seconds and p=10^-6, TCP has an average window of 1200 packets. If the packet size is 1500 bytes, then TCP can achieve an average rate of 1.44 Gbps. In this case, CUBIC with C=0.04 or C=0.4 achieves exactly the same rate as Standard TCP, whereas HSTCP is about ten times more aggressive than Standard TCP.

We can see that C determines the aggressiveness of CUBIC in competing with other protocols for the bandwidth. CUBIC is more friendly to the Standard TCP, if the value of C is lower. However, we do not recommend to set C to a very low value like 0.04, since CUBIC with a low C cannot efficiently use the bandwidth in long RTT and high bandwidth networks. Based on these observations and our experiments, we find C=0.4 gives a good balance between TCP-friendliness and aggressiveness of window growth. Therefore, C SHOULD be set to 0.4.

With C set to 0.4, Eq. 6 is reduced to:

\[
AVG_W_{cubic} = 1.054 \times (RTT^{0.75}) / (p^{0.75}) \quad (Eq. 7)
\]

Eq. 7 is then used in the next subsection to show the scalability of CUBIC.

5.2. Using Spare Capacity

CUBIC uses a more aggressive window growth function than Standard TCP under long RTT and high bandwidth networks.
The following table shows that to achieve 10Gbps rate, standard TCP requires a packet loss rate of 2.0e-10, while CUBIC requires a packet loss rate of 2.9e-8.

Required packet loss rate for Standard TCP, HSTCP, and CUBIC to achieve a certain throughput. We use 1500-byte packets and an RTT of 0.1 seconds.

Table 3

Our test results in [HKLRX06] indicate that CUBIC uses the spare bandwidth left unused by existing Standard TCP flows in the same bottleneck link without taking away much bandwidth from the existing flows.

5.3. Difficult Environments

CUBIC is designed to remedy the poor performance of TCP in fast long-distance networks.

5.4. Investigating a Range of Environments

CUBIC has been extensively studied by using both NS-2 simulation and test-bed experiments covering a wide range of network environments. More information can be found in [HKLRX06].

Same as Standard TCP, CUBIC is a loss-based congestion control algorithm. Because CUBIC is designed to be more aggressive (due to faster window growth function and bigger multiplicative decrease factor) than Standard TCP in fast and long distance networks, it can fill large drop-tail buffers more quickly than Standard TCP and increase the risk of a standing queue [KWAF16]. In this case, proper queue sizing and management [RFC7567] could be used to reduce the packet queueing delay.
5.5. Protection against Congestion Collapse

With regard to the potential of causing congestion collapse, CUBIC behaves like standard TCP since CUBIC modifies only the window adjustment algorithm of TCP. Thus, it does not modify the ACK clocking and Timeout behaviors of Standard TCP.

5.6. Fairness within the Alternative Congestion Control Algorithm.

CUBIC ensures convergence of competing CUBIC flows with the same RTT in the same bottleneck links to an equal bandwidth share. When competing flows have different RTTs, their bandwidth shares are linearly proportional to the inverse of their RTT ratios. This is true independent of the level of statistical multiplexing in the link.

5.7. Performance with Misbehaving Nodes and Outside Attackers

This is not considered in the current CUBIC.

5.8. Behavior for Application-Limited Flows

CUBIC does not raise its congestion window size if the flow is currently limited by the application instead of the congestion window. In case of long periods when cwnd is not updated due to the application rate limit, such as idle periods, t in Eq. 1 MUST NOT include these periods; otherwise, W_{cubic}(t) might be very high after restarting from these periods.

5.9. Responses to Sudden or Transient Events

In case that there is a sudden congestion, a routing change, or a mobility event, CUBIC behaves the same as Standard TCP.

5.10. Incremental Deployment

CUBIC requires only the change of TCP senders, and does not require any assistant of routers.

6. Security Considerations

This proposal makes no changes to the underlying security of TCP.

7. IANA Considerations

There are no IANA considerations regarding this document.
