Guidelines on the cryptographic algorithms, accompanying the usage of standards GOST R 34.10-2012 and GOST R 34.11-2012
draft-smyshlyaev-gost-usage-10

Abstract

The purpose of this document is to make the specifications of the cryptographic algorithms defined by Russian national standards GOST R 34.10-2012 and GOST R 34.11-2012 available to the Internet community for their implementation in the cryptographic protocols based on the accompanying algorithms.

These specifications define the pseudorandom functions, the key agreement algorithm based on the Diffie-Hellman algorithm, the parameters of elliptic curves, the key derivation functions and the key export functions.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 14, 2016.
1. Introduction

The accompanying algorithms are intended for the cryptographic protocols implementation. This memo contains a description of the accompanying algorithms based on Russian national standards GOST R 34.10-2012 [GOST3410-2012] and GOST R 34.11-2012 [GOST3411-2012].
English versions of these standards can be found in [RFC7091] and [RFC6986].

The specifications of algorithms and parameters proposed in this memo are provided on the basis of experience in the development of the cryptographic protocols, as described in the [RFC4357], [RFC4490] and [RFC4491].

This memo describes the pseudorandom functions, the key agreement algorithm based on Diffie-Hellman algorithm, the parameters of elliptic curves, the key derivation functions, and the key export functions necessary to ensure interoperability of security protocols that make use of the Russian cryptographic standards GOST R 34.10-2012 [GOST3410-2012] digital signature algorithm and GOST R 34.11-2012 [GOST3411-2012] one-way hash function.

2. Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

3. Basic terms, definitions and notations

This document uses the following terms and definitions for the sets and operations on the elements of these sets:

(xor) exclusive-or of two binary vectors of the same length;

V_n the finite vector space over GF(2) of dimension n, n >= 0, with the (xor) operation; for n = 0 the V_0 space consists of a single empty element of size 0; if U is an element of V_n, then U = (u_(n-1), u_(n-2), ..., u_1, u_0), where u_i in {0, 1};

V_(8, r) the set of byte vectors of size r, r >= 0, for r = 0 the V_(8, r) set consists of a single empty element of size 0; if W is an element of V_(8, r), r > 0, then W = (w^0, w^1, ..., w^(r-1)), where w^0, w^1, ..., w^(r-1) are elements of V_8;

Bit representation the bit representation of the element W = (w^0, w^1, ..., w^(r-1)) of V_(8, r) is an element (w_(8r-1), w_(8r-2), ..., w_1, w_0) of V_(8*r), where w^0 = (w_7, w_6, ..., w_0), w^1 = (w_15, w_14, ..., w_8), ..., w^(r-1) = (w_(8r-1), w_(8r-2), ..., w_(8r-8)) are elements of V_8;

Byte representation if n is a multiple of 8, r = n/8, then the byte representation of the element W = (w_(n-1), w_(n-2), ...,
w_0) of V_n is a byte vector (w^0, w^1, ..., w^(r-1)) of V_(8, r), where w^0 = (w_7, w_6, ..., w_0), w^1 = (w_15, w_14, ..., w_8), ..., w^(r-1) = (w_(8r-1), w_(8r-2), ..., w_(8r-8)) are elements of V_8;

A|B     concatenation of vectors A and B, i.e., if A in V_n1, B in V_n2, A = (a_(n1-1), a_(n1-2), ..., a_0), and B = (b_(n2-1), b_(n2-2), ..., b_0), then A|B = (a_(n1-1), a_(n1-2), ..., a_0, b_(n2-1), b_(n2-2), ..., b_0) is an element of V_(n1+n2); if A in V_(8, r1), B in V_(8, r2), A = (a^0, a^1, ..., a^(r1-1)), and B = (b^0, b^1, ..., b^(r2-1)), then A|B = (a^0, a^1, ..., a^(r1-1), b^0, b^1, ..., b^(r2-1)) is an element of V_(8, r1+r2);

K (key) an arbitrary element of V_n; if K in V_n, then its size (in bits) is equal to n, where n can be an arbitrary natural number.

This memo uses the following abbreviations and symbols:

<table>
<thead>
<tr>
<th>Symbols</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>H_256</td>
<td>GOST R 34.11-2012 hash function with 256-bit output</td>
</tr>
<tr>
<td>H_512</td>
<td>GOST R 34.11-2012 hash function with 512-bit output</td>
</tr>
<tr>
<td>HMAC</td>
<td>a function for calculating a message authentication code, based on a hash function in accordance with [RFC2104]</td>
</tr>
<tr>
<td>PRF</td>
<td>a pseudorandom function, i.e., a transformation that allows to generate pseudorandom sequence of bytes</td>
</tr>
<tr>
<td>KDF</td>
<td>a key derivation function, i.e., a transformation that allows to derive keys and keying material from the root key and additional input using a pseudorandom function</td>
</tr>
<tr>
<td>VKO</td>
<td>a key agreement algorithm based on the Diffie-Hellman transformation and a hash function.</td>
</tr>
</tbody>
</table>

To generate a byte sequence of the size r with functions that give a longer output the output is truncated to the first r bytes. This remark applies to the following functions:

- the functions described in Section 4.2;
The concatenation operation (|) can be applied to vectors either in bit or byte representation, depending on the form of the arguments. When the concatenation operation (|) is applied to two vectors in bit representation, the result is a vector in bit representation. When the concatenation operation (|) is applied to two vectors in byte representation, the result is a vector in byte representation. Thus, the operation is uniquely determined by the representation of arguments.

Hereinafter all data are provided in byte representation unless otherwise specified. Therefore, the arguments to the concatenation operation (|) are vectors in byte representation unless explicitly stated otherwise.

If a function is defined outside this document (e.g., H_256) and its definition requires arguments in bit representation, it is assumed that the bit representations of the arguments are formed immediately before the calculation of the function (in particular, immediately after the application of the operation (|) to the byte representation of the arguments).

If the output of another function defined outside of this document is used as an argument of the functions defined below, and it has the bit representation, then it is assumed that the output value must have a multiple of 8 length and that it will be translated into the byte representation in advance.

4. Algorithm descriptions

4.1. HMAC functions

This section defines the HMAC transformations based on the GOST R 34.11-2012 [GOST3411-2012] algorithm.

4.1.1. HMAC_GOSTR3411_2012_256

This HMAC transformation is based on the GOST R 34.11-2012 [GOST3411-2012] hash-function with 256-bit output. The object identifier of this transformation is shown below:

\[
\text{id-tc26-hmac-gost-3411-12-256}::= \{\text{iso(1) member-body(2) ru(643) rosstandart(7) tc26(1) algorithms(1) mac(4) hmac-gost-3411-12-256(1)}\}
\]

This algorithm uses H_256 as a hash function for HMAC, described in [RFC2104]. The method of forming the values of ipad and opad is also
specified in [RFC2104]. The size of HMAC_GOSTR3411_2012_256 output is equal to 32 bytes, the block size of the iterative procedure for the H_256 compression function is equal to 64 bytes (in the notation of [RFC2104], \( L = 32 \) and \( B = 64 \), respectively).

4.1.2. HMAC_GOSTR3411_2012_512

This HMAC transformation is based on the GOST R 34.11-2012 [GOST3411-2012] hash-function with 512-bit output. The object identifier of this transformation is shown below:

\[
\text{id-tc26-hmac-gost-3411-12-512::= \{iso(1) member-body(2) ru(643) rosstandart(7) tc26(1) algorithms(1) mac(4) hmac-gost-3411-12-512(2)\}}.
\]

This algorithm uses \( \text{H}_{512} \) as a hash function for HMAC, described in [RFC2104]. The method of forming the values of ipad and opad is also specified in [RFC2104]. The size of HMAC_GOSTR3411_2012_512 output is equal to 64 bytes, the block size of the iterative procedure for the \( \text{H}_{512} \) compression function is equal to 64 bytes (in the notation of [RFC2104], \( L = 64 \) and \( B = 64 \), respectively).

4.2. Pseudorandom functions

This section defines six HMAC-based PRF transformations recommended for usage. Two of them are designed for the TLS protocol and four are designed for the IPsec protocol.

4.2.1. PRFs for the TLS protocol

4.2.1.1. PRF_TLS_GOSTR3411_2012_256

This is the transformation providing the pseudorandom function for the TLS protocol (1.0 and higher versions) in accordance with GOST R 34.11-2012 [GOST3411-2012]. It uses the \( \text{P}_{GOSTR3411_2012_256} \) function that is similar to the \( \text{P}_{hash} \) function defined in Section 5 of [RFC2246], where HMAC_GOSTR3411_2012_256 function (defined in Section 4.1.1 of this document) is used as the \( \text{H}_{hash} \) function.

\[
\text{PRF_TLS_GOSTR3411_2012_256 (secret, label, seed)} = \\
\text{P}_{GOSTR3411_2012_256 (secret, label \mid seed)}.
\]

In order to avoid possible collisions label and seed values must be assigned by a protocol, their lengths must be fixed by a protocol.
4.2.1.2. PRF_TLS_GOSTR3411_2012_512

This is the transformation providing the pseudorandom function of the TLS protocol (1.0 and higher versions) in accordance with GOST R 34.11-2012 [GOST3411-2012]. It uses the P_GOSTR3411_2012_512 function that is similar to the P_hash function defined in Section 5 of [RFC2246], where HMAC_GOSTR3411_2012_512 function (defined in Section 4.1.2 of this document) is used as the HMAC_hash function.

\[
\begin{align*}
\text{PRF_TLS_GOSTR3411_2012_512} = \text{P_GOSTR3411_2012_512} (\text{secret, label | seed}) = \\
= \text{P_GOSTR3411_2012_512} (\text{secret, label}, \text{seed}).
\end{align*}
\]

In order to avoid possible collisions label and seed values must be assigned by a protocol, their lengths must be fixed by a protocol.

4.2.2. PRFs for the IPsec protocols based on GOST R 34.11-2012

IPsec family protocols use the pseudorandom functions for the purposes of keying material generation and authentication. The specifications for the version 1 (IKEv1) [RFC2409] and version 2 (IKEv2) [RFC7296] of the Internet Key Exchange protocol contain definitions of using PRF in various parts of the protocols.

4.2.2.1. PRF in the IKEv1 protocol

According to the Section 4 of [RFC2409] if a PRF is not negotiated, the HMAC based on the negotiated hash algorithm is used. So, when GOST R 34.11-2012 [GOST3411-2012] is used as a hash function in IKEv1, HMAC_GOST3411_2012_512 is used as a PRF.

4.2.2.2. PRF in the IKEv2 protocol

IKEv2 has no default PRF. This document specifies that either HMAC_GOST3411_2012_256 or HMAC_GOST3411_2012_512 must be used as PRF for the IKEv2 protocol.

4.3. VKO algorithms for key agreement

This section specifies the key agreement algorithms based on GOST R 34.10-2012 [GOST3410-2012].

4.3.1. VKO_GOSTR3410_2012_256

The VKO_GOSTR3410_2012_256 transformation is used for an agreement of the VKO 256-bit keys and is based on the 256-bit version of GOST R 34.11-2012 [GOST3411-2012]. This algorithm can be applied for a key agreement using GOST R 34.10-2012 [GOST3410-2012] with 256-bit and 512-bit keys.
The algorithm is designed to produce an encryption key or a keying material of size 256 bits to be used in various cryptographic protocols. Key or keying material \( KEK_{VKO} (x, y, UKM) \) is generated from the private key \( x \) of one side, the public key \( y*P \) of the opposite side and the UKM value, considered as a number.

The algorithm can be used for deriving both static and ephemeral key with the public key size \( n \geq 512 \) bits including the case where one side uses a static key and the other - ephemeral.

UKM parameter is optional (the default UKM = 1) and can take any value from 1 to \( 2^{(n/2)} - 1 \). It is allowed to use a nonzero UKM of arbitrary size not exceeding \( n/2 \) bits. If at least one of the parties uses static keys, the recommended length of UKM is 64 bits or more.

\( KEK_{VKO} (x, y, UKM) \) is calculated using the formulas

\[
KEK_{VKO} (x, y, UKM) = H_{256} (K (x, y, UKM)),
\]

\[
K (x, y, UKM) = (m/q*UKM*x \mod q)^*(y*P),
\]

where \( m \) and \( q \) are the parameters of elliptic curve defined in the GOST R 34.10-2012 [GOST3411-2012] standard (\( m \) is an elliptic curve points group order, \( q \) is an order of a cyclic subgroup).

This algorithm is defined similar to one specified in Section 5.2 of [RFC4357], but applies the hash function \( H_{256} \) instead of the hash function GOST R 34.11-94 [GOST3411-94] (referred as gostR3411). In addition, \( K(x, y, UKM) \) is calculated with public key size \( n \geq 512 \) bits and UKM has size up to \( n/2 \) bits.

4.3.2. VKO_GOSTR3410_2012_512

The VKO_GOSTR3410_2012_512 transformation is used for an agreement of the VKO 512-bit keys and is based on the 256-bit version of GOST R 34.10-2012 [GOST3411-2012], 512-bit. This algorithm can be applied for a key agreement using GOST R 34.10-2012 [GOST3410-2012] with 512-bit keys.

The algorithm is designed to produce an encryption key or keying material of size 512 bits to be used in cryptographic protocols. Key or keying material \( KEK_{VKO} (x, y, UKM) \) is generated from the private key \( x \) of one side, the public key \( y*P \) of the opposite side and the UKM value, considered as a number.
The algorithm can be used for both static and ephemeral key with the public key size \( n \geq 1024 \) bits including the case where one side uses a static key and the other uses an ephemeral one.

UKM parameter is optional (the default UKM = 1) and can take any value from 1 to \( 2^{(n/2)}-1 \). It is allowed to use a nonzero UKM of arbitrary size not exceeding \( n/2 \) bits. If at least one of the parties uses static keys, the recommended length of UKM is 128 bits or more.

\[
\text{KEK}_\text{VKO} (x, y, \text{UKM}) \text{ is calculated using the formulas}
\]

\[
\text{KEK}_\text{VKO} (x, y, \text{UKM}) = H_{512} (K (x, y, \text{UKM})),
\]

\[
K (x, y, \text{UKM}) = (m/q*\text{UKM}*x \mod q)*(y*P),
\]

where \( m \) and \( q \) are the parameters of elliptic curve defined in the GOST R 34.10-2012 [GOST3411-2012] standard (\( m \) is an elliptic curve points group order, \( q \) is an order of a cyclic subgroup).

This algorithm is defined similar to one specified in Section 5.2 of [RFC4357], but applies the hash function \( H_{512} \) instead of the hash function GOST R 34.11-94 [GOST3411-94] (referred as gostR3411). In addition, \( K(x, y, \text{UKM}) \) is calculated with public key size \( n \geq 1024 \) bits and UKM has size up to \( n/2 \) bits.

### 4.4. The key derivation function \text{KDF_TREE_GOSTR3411_2012_256}

The key derivation function \text{KDF_TREE_GOSTR3411_2012_256} based on the \text{HMAC_GOSTR3411_2012_256} function is given by:

\[
\text{KDF_TREE_GOSTR3411_2012_256} (\text{K_in}, \text{label}, \text{seed}, R) = K(1)| K(2)| K(3)| K(4)|...,
\]

\[
K(i) = \text{HMAC_GOSTR3411_2012_256} (\text{K_in}, [i]_b | \text{label} | 0x00 | \text{seed}| [L]_2), i \geq 1,
\]

where

\[
\text{K_in} \quad \text{derivation key;}
\]

\[
\text{label, seed} \quad \text{the parameters that must be assigned by a protocol, their lengths must be fixed by a protocol;}
\]

\[
\text{R} \quad \text{a fixed external parameter, with possible values of 1, 2, 3 or 4;}
\]

\[
\text{i} \quad \text{iteration counter;}
\]
[i]_b  byte representation of the iteration counter (in the network byte order), the number of bytes in the representation [i]_b is equal to R (no more than 4 bytes);

L  the required size (in bits) of the generated keying material (an integer, not exceeding 256*(2^(8*R)-1));

[L]_b  byte representation of L, in network byte order (variable length: no leading zero bytes added).

The key derivation function KDF_TREE_GOSTR3411_2012_256 is intended for generating a keying material in size of L, not exceeding 256*(2^(8*R)-1) bits, and utilizes general principles of the input and output for the key derivation function outlined in Section 5.1 of NIST SP 800-108 [NISTSP800-108]. HMAC_GOSTR3411_2012_256 algorithm described in Section 4.1.1 is selected as a pseudorandom function.

Each key derived from the keying material formed using the derivation key K_in (0-level key) may be a 1-level derivation key and may be used to generate a new keying material. The keying material derived from the 1-level derivation key can be split down into the 2nd level derivation keys. The application of this procedure leads to the construction of the key tree with the root key and the formation of the keying material to the hierarchy of the levels, as described in Section 6 of NIST SP 800-108 [NISTSP800-108]. The partitioning procedure for keying material at each level is defined in accordance with a specific protocols.

4.5. The key derivation function KDF_GOSTR3411_2012_256

When R = 1 and L = 256 the function KDF_TREE_GOSTR3411_2012_256 is equivalent to the KDF_GOSTR3411_2012_256 function that is given by:

\[
\text{KDF_GOSTR3411_2012_256} (K_{in}, \text{label}, \text{seed}) = \\
\text{HMAC_GOSTR3411_2012_256} (K_{in}, 0x01 | \text{label} | 0x00 | \text{seed} | 0x01 | 0x00),
\]

where

- K_in -- derivation key,

- label, seed -- the parameters that must be assigned by a protocol, their lengths must be fixed by a protocol.
4.6. Key wrap and key unwrap

Wrapped representation of the secret key K (256-bit GOST 28147-89 [GOST28147-89] key, 256-bit or 512-bit GOST R 34.10-2012 [GOST3410-2012] key) is formed as follows by using a given export key K_e (GOST 28147-89 [GOST28147-89] key) and a random seed vector:

1. Generate a random seed vector from 8 to 16 bytes.

2. With the key derivation function, using an export key K_e as a derivation key, generate a key, denoted by KEK_e (seed), where

   \[ KEK_e (seed) = KDF_{GOSTR3411_2012_256} (K_e, label, seed), \]

   where the KDF_{GOSTR3411_2012_256} function (see Section 4.5) is used as a key derivation function for the fixed label value

   \[ label = (0x26 \ | \ 0xBD \ | \ 0xB8 \ | \ 0x78). \]

3. MAC value GOST 28147-89 (4-byte) for the data K and the key KEK_e (seed) is calculated, initialization vector (IV) in this case is equal to the first 8 bytes of seed. The resulting value is denoted as CEK_MAC.

4. The key K is encrypted by the GOST 28147-89 algorithm in the Electronic Codebook (ECB) mode with the key KEK_e (seed). The encoding result is denoted as CEK_ENC.

5. The wrapped representation of the key is considered (seed | CEK_ENC | CEK_MAC).

During the key import the value of key K is restored as follows from the wrapped representation of the key and the export key K_e:

1. From the wrapped representation of the key select the sets seed, CEK_ENC, and CEK_MAC.

2. With the key derivation function, using the export key K_e as a derivation key, generate a key, denoted by KEK_e(seed), where

   \[ KEK_e (seed) = KDF_{GOSTR3411_2012_256} (K_e, label, seed), \]

   where the KDF_{GOSTR3411_2012_256} function (see section Section 4.5) is used as a key derivation function for the fixed label value

   \[ label = (0x26 \ | \ 0xBD \ | \ 0xB8 \ | \ 0x78). \]
3. The CEK_ENC set is decrypted by the GOST 28147-89 algorithm in
the Electronic Codebook (ECB) mode with the key KEK_e(seed). The
unwrapped key K is assumed to be equal to the result of
decryption.

4. MAC value GOST 28147-89 (4-byte) for the data K and the key
KEK_e(seed) is calculated, initialization vector (IV) in this
case is equal to the first 8 bytes of seed. If the result does
not equal to CEK_MAC, an error is returned.

GOST 28147-89 algorithm is used with the S-box defined in Appendix C
of this document.

5. The parameters of elliptic curves

This section defines the elliptic curves parameters and object
identifiers that are recommended for the usage with signature and
verification algorithms of digital signature in accordance with GOST
R 34.10-2012 [GOST3410-2012] standard and with the key agreement
algorithms VKO_GOSTR3410_2012_256 and VKO_GOSTR3410_2012_512.

This document does not negate the use of other parameters of the
elliptic curves.

5.1. Canonical form

This section defines the elliptic curves parameters of the GOST R
34.10-2012 [GOST3410-2012] standard for the case of elliptic curves
with prime 512-bit moduli in canonical (Weierstrass) form, that is
given by the following equation defined in GOST R 34.10-2012
[GOST3410-2012]:

\[ y^2 = x^3 + ax + b. \]

In case of an elliptic curves with 256-bit prime moduli the
parameters defined in [RFC4357] are proposed to use.

5.1.1. Parameters and object identifiers

The parameters for each elliptic curve are represented by the
following values which are defined in GOST R 34.10-2012
[GOST3410-2012]:

\[ p \] the elliptic curve modulus;
\[ a, b \] the coefficients of the equation of the elliptic curve in the
canonical form;
q     the order of the elliptic curve;
(x, y) the coordinates of a point P (generator of the prime order
group) of the elliptic curve in the canonical form.

Both sets of the parameters are presented as ASN structures of the
form:

SEQUENCE {
a    INTEGER,
b    INTEGER,
p    INTEGER,
q    INTEGER,
x    INTEGER,
y    INTEGER
}

The parameter sets have the following object identifiers:

1. id-tc26-gost-3410-12-512-paramSetA::= {iso(1) member-body(2)
   ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1)
   gost-3410-12-512-constants(2) paramSetA(1)};

2. id-tc26-gost-3410-12-512-paramSetB::= {iso(1) member-body(2)
   ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1)
   gost-3410-12-512-constants(2) paramSetB(2)}.

Corresponding values of the parameter sets can be found in
Appendix A.1.

5.2. Twisted Edwards form

This section defines the elliptic curves parameters and object
identifiers of the GOST R 34.10-2012 [GOST3410-2012] standard for the
case of elliptic curves that have a representation in the Twisted
Edwards form with a prime 256-bit and 512-bit moduli.

A Twisted Edwards curve E over a finite prime field F_p, p > 3, is an
elliptic curve defined by the equation:

\[ e*u^2 + v^2 = 1 + d*u^2*v^2, \]

where e, d are in F_p, ed(e-d) != 0.

A Twisted Edwards curve has an equivalent representation in the
Weierstrass form defined by parameters a, b. The parameters a, b, e
and d are related as follows:
\[ \begin{align*}
    a &= s^2 - 3t^2, \\
    b &= 2t^3 - t^2s^2,
\end{align*} \]

where

\[ \begin{align*}
    s &= (e - d) / 4, \\
    t &= (e + d) / 6.
\end{align*} \]

Coordinate transformations are defined as follows:

\[ \begin{align*}
    (u, v) \rightarrow (x, y) &= (s(1 + v) / (1 - v) + t, s(1 + v) / ((1 - v)u)) , \\
    (x, y) \rightarrow (u, v) &= ((x - t) / y, (x - t - s) / (x - t + s)) .
\end{align*} \]

5.2.1. Parameters and object identifiers

The parameters for each elliptic curve are represented by the following values which are defined in GOST R 34.10-2012 [GOST3410-2012]:

- **p** the elliptic curve modulus;

- **a, b** the coefficients of the equation of the elliptic curve in the canonical form;

- **e, d** the coefficients of the equation of the elliptic curve in the Twisted Edwards form;

- **m** the elliptic curve group order;

- **q** the elliptic curve subgroup order;

- **(x, y)** the coordinates of a point \( P \) (generator of the prime order group) of the elliptic curve in the canonical form;

- **(u, v)** the coordinates of a point \( P \) (generator of the prime order group) of the elliptic curve in the Twisted Edwards form.
Both sets of the parameters are presented as ASN structures of the form:

```
SEQUENCE {
p          INTEGER,
a          INTEGER,
b          INTEGER,
e          INTEGER,
d          INTEGER,
m          INTEGER,
q          INTEGER,
x          INTEGER,
y          INTEGER,
u          INTEGER,
v          INTEGER
}
```

The parameter sets have the following object identifiers:

1. `id-tc26-gost-3410-2012-256-paramSetA ::= {iso(1) member-body(2)
ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1)
gost-3410-12-256-constants(1) paramSetA(1)};`

2. `id-tc26-gost-3410-2012-512-paramSetC ::= {iso(1) member-body(2)
ru(643) rosstandart(7) tc26(1) constants(2) sign-constants(1)
gost-3410-12-512-constants(2) paramSetC(3)};`

Corresponding values of the parameter sets can be found in Appendix A.2.

6. Acknowledgments

We thank Valery Smyslov, Igor Ustinov, Basil Dolmatov and Russ Housley for their careful readings and useful comments.

Appendix C. GOST 28147-89 parameter set

The parameter set has the following object identifier:

```
1. id-tc26-gost-28147-param-Z::= {iso(1) member-body(2) ru(643)
   rosstandart(7) tc26(1) constants(2) cipher-constants(5) gost-
   28147-constants(1) param-Z(1)}
```

The parameter set is defined bellow:
<table>
<thead>
