The Security Evaluated Standardized Password Authenticated Key Exchange
(SESPAKE) Protocol
draft-smyshlyaev-sespake-03

Abstract

This document specifies the Security Evaluated Standardized Password Authenticated Key Exchange (SESPAKE) protocol. The SESPAKE protocol provides password authenticated key exchange for usage in the systems for protection of sensitive information. The security proofs of the protocol was made for the case of an active adversary in the channel, including MitM attacks and attacks based on the impersonation of one of the subjects.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on November 5, 2016.

1. Introduction

The current document contains the description of the password authenticated key exchange protocol SESPAKE (security evaluated standardized password authenticated key exchange) for usage in the systems for protection of sensitive information. The protocol is intended to use for establishment of keys that are then used for organization of secure channel for protection of sensitive information. The security proofs of the protocol was made for the case of an active adversary in the channel, including MitM attacks and attacks based on the impersonation of one of the subjects.

2. Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

3. Notations

This document uses the following parameters of elliptic curves in accordance with [RFC6090].

E an elliptic curve defined over a finite prime field $GF(p)$, where $p > 3$;

p the characteristic of the underlying prime field;

a, b the coefficients of the equation of the elliptic curve in the canonical form;

m the elliptic curve group order;

q the elliptic curve subgroup order;

P generator of the subgroup of order q;

X, Y the coordinates of the elliptic curve point in the canonical form;

O zero point (point of infinity) of the elliptic curve.

This memo uses the following functions:

HASH the underlying hash function;

HMAC the function for calculating a message authentication code, based on a HASH function in accordance with [RFC2104];

$F(PW, salt, n)$ the value of the function $PBKDF2(PW, salt, n, len)$, where $PBKDF2(PW, salt, n, len)$ is calculated according to [RFC2898] The parameter len is considered equal to minimal integer that is a multiple of 8 and satisfies the following condition:
 $len \geq \text{floor}(\log_2(q))$.

This document uses the following terms and definitions for the sets and operations on the elements of these sets

B_n the set of byte strings of size n, $n \geq 0$, for $n = 0$ the B_n set consists of a single empty string of size 0; if b is an element of B_n , then $b = (b_1, \dots, b_n)$, where b_1, \dots, b_n are elements of $\{0, \dots, 255\}$;

$\text{int}(w')$ if the byte string $w' = (w_1, \dots, w_t)$ is in B_t , then $\text{int}(w')$ is an integer $w = 256^{(t-1)}w_t + \dots + 256^{(0)}w_1$;

$\text{INT}(w')$ if the byte string $w' = (w_1, \dots, w_t)$ is in B_t , then $\text{INT}(w')$ is an integer $W = 256^{(t-1)}w_1 + \dots + 256^{(0)}w_t$;

|| concatenation of byte strings A and C, i.e., if A in B_{n1} , C in B_{n2} , $A = (a_1, a_2, \dots, a_{n1})$ and $C = (c_1, c_2, \dots, c_{n2})$, then $A||C = (a_1, a_2, \dots, a_{n1}, c_1, c_2, \dots, c_{n2})$ is an element of $B_{(n1+n2)}$;

Byte representation of a point (X,Y) If (X, Y) is an elliptic curve point then the byte representation of (X,Y) is a concatenation of the coordinates of this point $X||Y$; the length of the byte representations of the coordinates X and Y is equal to the minimum possible length of the byte representation of the subgroup generator p.

4. Mathematical definitions

Suppose a prime number $p > 3$ is given. Then, an elliptic curve E, defined over a finite prime field $GF(p)$, is the set of number pairs (x,y) , where x and y belong to F_p , satisfying the identity:

$$y^2 = x^3 + a * x + b \pmod{p},$$

where a, b belong to $GF(p)$ and $4 * a^3 + 27 * b^2$ is not congruent to zero modulo p.

An invariant of the elliptic curve is the value $J(E)$, satisfying the equality:

$$J(E) = 1728 * \frac{4 * a^3}{4 * a^3 + 27 * b^2} \pmod{p},$$

Elliptic curve E coefficients a, b are defined in the following way using the invariant $J(E)$:

$$\begin{cases} a = 3 * k \pmod{p}, \\ b = 2 * k \pmod{p}, \end{cases}$$

where $k = \frac{J(E)}{1728 - J(E)} \pmod{p}$, $J(E) \neq 0$ or 1728.

The pairs (x, y) satisfying the identity (1) are called "the elliptic curve E points"; x and y are called x- and y-coordinates of the point, correspondingly.

We will denote elliptic curve points as $Q(x, y)$ or just Q. Two elliptic curve points are equal if their x- and y-coordinates are equal.

On the set of all elliptic curve E points, we will define the addition operation, denoted by "+". For two arbitrary elliptic curve E points Q1 (x1, y1) and Q2 (x2, y2), we will consider several variants.

Suppose coordinates of points Q1 and Q2 satisfy the condition $x1 \neq x2$. In this case, their sum is defined as a point Q3 (x3, y3), with coordinates defined by congruencies:

$$\begin{cases} x3 = \text{lambda}^2 - x1 - x2 \pmod{p}, \\ y3 = \text{lambda} * (x1 - x3) - y1 \pmod{p}, \end{cases}$$

$$\text{where } \text{lambda} = \frac{y1 - y2}{x1 - x2} \pmod{p}.$$

If $x1 = x2$ and $y1 = y2 \neq 0$, then we will define point Q3 coordinates in the following way:

$$\begin{cases} x3 = \text{lambda}^2 - x1 * 2 \pmod{p}, \\ y3 = \text{lambda} * (x1 - x3) - y1 \pmod{p}, \end{cases}$$

$$\text{where } \text{lambda} = \frac{3 * x1^2 + a}{y1 * 2} \pmod{p}.$$

If $x1 = x2$ and $y1 = -y2 \pmod{p}$, then the sum of points Q1 and Q2 is called a zero point O, without determination of its x- and y-coordinates. In this case, point Q2 is called a negative of point Q1. For the zero point, the equalities hold:

$$O + Q = Q + O = Q,$$

where Q is an arbitrary point of elliptic curve E.

A set of all points of elliptic curve E, including the zero point, forms a finite abelian (commutative) group of order m regarding the introduced addition operation. For m, the following inequalities hold:

$$p + 1 - 2 * \text{sqrt}(p) \leq m \leq p + 1 + 2 * \text{sqrt}(p).$$

The point Q is called "a point of multiplicity k", or just "a multiple point of the elliptic curve E", if for some point P, the following equality holds:

$$Q = P + \dots + P = k * P$$

-----+-----
k

5. Protocol description

The protocol is used by subjects A and B that are commencing key establishment with password-based authentication.

5.1. Protocol parameters

Various elliptic curves can be used in the protocol. For each elliptic curve supported by clients the following values must be defined:

- o the curve identifier ID_ALG, that is a byte string of arbitrary length;
- o the point P, that is a generator point of the subgroup of order q of the curve;
- o the set of distinct curve points {Q_1, Q_2, ..., Q_N} of order q, where the total number of points N is defined for protocol instance.

The method of generation of the points {P, Q_1, Q_2, ..., Q_N} is described in Section 6.

The protocol parameters that are used by subject A are the following:

1. The secret password value PW, which is a byte string that is uniformly randomly chosen from a subset of cardinality 10^{10} or greater of the set B_k , where $k \geq 6$ is password length.
2. The list of curve identifiers supported by A.
3. Sets of points {Q_1, Q_2, ..., Q_N}, corresponding to curves supported by A.
4. The C_1^A counter, that tracks the total number of unsuccessful authentication trials in a row, and a value of CLim_1 that stores the maximum possible number of such events.
5. The C_2^A counter, that tracks the total number of unsuccessful authentication events during the period of usage of the specific PW, and a value of CLim_2 that stores the maximum possible number of such events.

6. The C_3^A counter, that tracks the total number of authentication events (successful and unsuccessful) during the period of usage of the specific PW, and a value of $CLim_3$ that stores the maximum possible number of such events. The identifier ID_A of subject A (optional), a byte string of an arbitrary length.
7. The unique identifier ID_A of the subject A (optional, see. Note 2), which is a byte string of an arbitrary length.

The protocol parameters that are used by subject B are the following:

1. The values ind and $salt$, where ind is in $\{1, \dots, N\}$, $salt$ is in $\{1, \dots, 2^{128}-1\}$.
2. The point Q_{PW} , satisfying the following equation:

$$Q_{PW} = \text{int} (F (PW, salt, 2000)) * Q_{ind}.$$

It is possible that the point Q_{PW} is not stored and is calculated using PW in the beginning of the protocol. In that case B has to store PW and points Q_1, Q_2, \dots, Q_N .

3. The ID_{ALG} identifier of the elliptic curve used in the protocol.
4. The C_1^B counter, that tracks the total number of unsuccessful authentication trials in a row, and a value of $CLim_1$ that stores the maximum possible number of such events.
5. The C_2^B counter, that tracks the total number of unsuccessful authentication events during the period of usage of the specific PW, and a value of $CLim_2$ that stores the maximum possible number of such events.
6. The C_3^B counter, that tracks the total number of authentication events (successful and unsuccessful) during the period of usage of the specific PW, and a value of $CLim_3$ that stores the maximum possible number of such events. The identifier ID_B of subject B (optional), a byte string of an arbitrary length.
7. The unique identifier ID_B of the subject B (optional, see. Note 2), which is a byte string of an arbitrary length.

5.2. Initial values of the protocol counters

After the setup of a new password value PW the values of the counters must be assigned as follows:

- o $C_1^A = C_1^B = CLim_1$, where $CLim_1$ is in $\{3, \dots, 5\}$;

- o $C_2^A = C_2^B = \text{CLim}_2$, where CLim_2 is in $\{7, \dots, 20\}$;
- o $C_3^A = C_3^B = \text{CLim}_3$, where CLim_3 is in $\{10^3, 10^3+1, \dots, 10^5\}$.

5.3. Protocol steps

The described protocol consists of the following steps:

1. If any of the counters C_1^A , C_2^A , C_3^A is equal to 0, A finishes the protocol with an error that informs of exceeding the number of trials that is controlled by the corresponding counter.
2. A decrements each of the counters C_1^A , C_2^A , C_3^A by 1, requests open authentication information from B and sends the ID_A identifier.
3. If any of the counters C_1^B , C_2^B , C_3^B is equal to 0, B finishes the protocol with an error that informs of exceeding the number of trials that is controlled by the corresponding counter.
4. B decrements each of the counters C_1^B , C_2^B , C_3^B by 1.
5. B sends the values of ind , salt and the ID_ALG identifier to A. B also can **OPTIONALLY** send the ID_B identifier to A. All following calculations are done by B in the elliptic curve group defined by the ID_ALG identifier.
6. A sets the curve defined by the received ID_ALG identifier as the used elliptic curve. All following calculations are done by A in this elliptic curve group.
7. A calculates the point $Q_{\text{PW}}^A = \text{int}(F(\text{PW}, \text{salt}, 2000)) * Q_{\text{ind}}$.
8. A chooses randomly (according to the uniform distribution) the value α , α is in $\{1, \dots, q-1\}$, and assigns $z_A = 0$.
9. A sends the value $u_1 = \alpha * P - Q_{\text{PW}}^A$ to B.
10. After receiving u_1 , B checks that u_1 is in E . If it is not, B finishes with an error, considering the authentication process unsuccessful.
11. B calculates $Q_B = u_1 + Q_{\text{PW}}$, assigns $z_B = 0$ and chooses randomly (according to the uniform distribution) the value β , β is in $\{1, \dots, q-1\}$.

12. If $m/q * Q_B = 0$, B assigns $Q_B = P$ and $z_B = 1$.
13. B calculates $K_B = \text{HASH}((m/q * \text{beta} * (\text{mod } q)) * Q_B)$, where the input of a hash function is a little-endian representation of the obtained point (x-coordinate first, then y-coordinate).
14. B sends the value $u_2 = \text{beta} * P + Q_{PW}$ to A.
15. After receiving u_2 , A checks that u_2 is in E. If it is not, A finishes with an error, considering the authentication process unsuccessful.
16. A calculates $Q_A = u_2 - Q_{PW}^A$.
17. If $m/q * Q_A = 0$, then A assigns $Q_A = P$ and $z_A = 1$.
18. A calculates $K_A = \text{HASH}((m/q * \text{alpha} * (\text{mod } q)) * Q_A)$, where the input of a hash function is a little-endian representation of the obtained point (x-coordinate first, then y-coordinate).
19. A calculates $\text{MAC}_A = \text{HMAC}(K_A, 0x01 || \text{ID}_A || \text{ind} || \text{salt} || u_1 || u_2 || \text{DATA}_A)$, where DATA_A is an optional string that is authenticated with MAC_A (if it is not used, then DATA_A is considered to be of zero length).
20. A sends ($\text{DATA}_A || \text{MAC}_A$) to B.
21. B checks that the values MAC_A and $\text{HMAC}(K_B, 0x01 || \text{ID}_A || \text{ind} || \text{salt} || u_1 || u_2 || \text{DATA}_A)$ are equal. If they are not, it finishes with an error, considering the authentication process unsuccessful.
22. If $z_B = 1$, B finishes, considering the authentication process unsuccessful.
23. B sets the value of C_1^B to CLim_1 and increases C_2^B by 1.
24. B calculates $\text{MAC}_B = \text{HMAC}(K_B, 0x02 || \text{ID}_B || \text{ind} || \text{salt} || u_1 || u_2 || \text{DATA}_A || \text{DATA}_B)$, where DATA_B is an optional string that is authenticated with MAC_B (if it is not used, then DATA_B is considered to be of zero length).
25. B sends ($\text{DATA}_B || \text{MAC}_B$) to A.
26. A checks that the values MAC_B and $\text{HMAC}(K_A, 0x02 || \text{ID}_B || \text{ind} || \text{salt} || u_1 || u_2 || \text{DATA}_A || \text{DATA}_B)$ are equal. If they are not, it finishes with an error, considering the authentication process unsuccessful.

27. If $z_A = 1$, A finishes, considering the authentication process unsuccessful.
28. A sets the value of C_1^A to $CLim_1$ and increases C_2^A by 1.

After the successful finish of the procedure the subjects A and B are mutually authenticated and each subject has an explicitly authenticated value of $K = K_A = K_B$.

N o t e:

1. In the case where the interaction process can be initiated by any subject (client or server) the ID_A and ID_B options MUST be used and the resiver MUST check that the identifier he had received is not equal to his own, otherwise, it finishes the protocol. If an optional parameter ID_A (or ID_B) is not used in the protocol, it SHOULD be considered equal to a fixed byte string (zero-length string is allowed) defined by a specific implementation.
2. The ind , ID_A , ID_B and salt parameters can be agreed in advance. If some parameter is agreed in advance, it is possible not to send it during a corresponding step. Nevertheless, all parameters MUST be used as corresponding inputs to HMAC function during stages 19, 21, 24 and 26.
3. The ID_ALG parameter can be fixed or agreed in advance.
4. Continuation of protocol interaction in case of any of the counters C_1^A , C_1^B being equal to zero MAY be done without changing password. In this case these counters can be used for protection against denial-of-service attacks. For example, continuation of interaction can be allowed after a certain delay.
5. Continuation of protocol interaction in case of any of the counters C_2^A , C_3^A , C_2^B , C_3^B being equal to zero MUST be done only after changing password.
6. Construction of points Q_1, \dots, Q_N

This section provides an example of possible algorithm for generation of each point Q_i in the set $\{Q_1, \dots, Q_N\}$ that corresponds to the given elliptic curve E.

The algorithm is based on choosing points with coordinates with a known preimages of a cryptographic hash function H, which is the GOST R 34.11-2012 hash function (see [RFC6986]) with 256-bit output, if $2^{254} < q < 2^{256}$, and the GOST R 34.11-2012 hash function (see [RFC6986]) with 512-bit output, if $2^{508} < q < 2^{512}$.

The algorithm consists of the following steps:

1. Choose an arbitrary SEED value with length of 32 bytes or more.
2. Calculate $X = \text{INT}(\text{H}(\text{SEED})) \bmod p$.
3. Check that the value of $X^3 + aX + b$ is a quadratic residue in the field F_p . If it is not, return to Step 1.
4. Choose the value of Y arbitrarily from the set $\{+\sqrt{A}, -\sqrt{A}\}$, where $A = X^3 + aX + b$. Here \sqrt{A} is an element of F_p , for which $(\sqrt{A})^2 = A \bmod p$.
5. Check that for point $Q = (X, Y)$ the following relations hold: $Q \neq 0$ and $q \cdot Q = 0$. If they do not, return to Step 1.

With the defined algorithm for any elliptic curve E point sets $\{Q_1, \dots, Q_N\}$ are constructed. Constructed points in one set MUST have distinct x-coordinates.

Note: The knowledge of hash function preimage prevents knowledge of the multiplicity of any point related to generator point P . It is of primary importance, because such a knowledge could be used to implement an attack against protocol with exhaustive search of password.

7. Acknowledgments

We thank Lolita Sonina, Georgy Borodin, Sergei Agafin and Ekaterina Smyshlyaeva for their careful readings and useful comments.

8. Security Considerations

Any cryptographic algorithms, particularly HASH function and HMAC function, that are used in the SESPAKE protocol MUST be carefully designed and MUST be able to withstand all known types of cryptanalytic attack.

It is RECOMMENDED that the HASH function satisfies the following condition:

$\text{hashlen} \leq \log_2(q) + 4$, where hashlen is the the lengths of the HASH function output.

The output lengths of hash functions that are used in the SESPAKE protocol is RECOMMENDED to be greater or equal to 256 bits.

The points Q_1, Q_2, \dots, Q_3 and P must be chosen in such a way that they are provable pseudorandomness. As a practical matter, this

means that the algorithm for generation of each point Q_i in the set $\{Q_1, \dots, Q_N\}$ (see Section 6) ensures that multiplicity of any point under any other point is unknown.

Appendix A. Test examples for GOST-based protocol implementation

The following test examples are made for the protocol implementation that is based on the Russian national standards GOST R 34.10-2012 [GOST3410-2012] and GOST R 34.11-2012 [GOST3411-2012]. The English versions of these standards can be found in [RFC7091] and [RFC6986].

A.1. Examples of points

There are three points (Q_1 , Q_2 , Q_3) for each of the elliptic curves below. This points were constructed using the method described in Section 6, where the GOST R 34.11-2012 hash function (see [RFC6986]) with 256-bit output is used if $2^{254} < q < 2^{256}$ and the GOST R 34.11-2012 hash function (see [RFC6986]) with 512-bit output is used if $2^{508} < q < 2^{512}$.

The same method should be used for constructing, if necessary, additional points. Each of the points complies with the GOST R 34.10-2012 [GOST3410-2012] standard and is represented by a pair of (X , Y) coordinates in the canonical form and by a pair of (U , V) coordinates in the twisted Edward form in accordance with the document [I-D.smyshlyaev-gost-usage] for the curves that have the equivalent representation in this form. There is a SEED value for each point, by which it was generated.

A.2. Test examples

This protocol implementation uses the GOST R 34.11-2012 hash function (see [RFC6986]) with 256-bit output as the H function and the HMAC_GOSTR3411_2012_512 function defined in [I-D.smyshlyaev-gost-usage] as a PRF function for the F function. The parameter len is considered equal to 256, if $2^{254} < q < 2^{256}$, and equal to 512, if $2^{508} < q < 2^{512}$.

The test examples for one of the three points of each curve in Appendix A.1 of this document are given below.

A.2.1 Curveid-GostR3410-2001-CryptoPro-A-ParamSet

The input protocol parameters in this example take the following values:

N= 3

ind= 1

ID_A:

00 00 00 00

ID_B:

00 00 00 00

PW:

31 32 33 34 35 36 ('123456')

salt:

29 23 be 84 e1 6c d6 ae 52 90 49 f1 f1 bb e9 eb

Q_ind:

X= 0xa33ce065b0c23e1d3d026a206f8a1f8747ed1cd92a665bf85198cdb10ac90a5c

Y= 0xb00d0dc0733883f05de9f55fd711f55998f5508cc40bead80c913b4d5b533667

The function F (PW, salt, 2000) takes the following values:

F(PW,salt,2000):

bd 04 67 3f 71 49 b1 8e 98 15 5b d1 e2 72 4e 71

d0 09 9a a2 51 74 f7 92 d3 32 6c 6f 18 12 70 67

The coordinates of the point Q_PW are:

X= 0x9d339b3396ae4a816388a14c79ab3a8dd495fa4c53f0d4076579022ef2aaeb68

Y= 0xdad91482e208590fd316bf959480f5ec2c17463ec8fc8f63030649b452cddda8

During the calculation of the message u_1 on the subject A the parameter alpha, the point alpha*P and the message u_1 take the following values:

alpha=0xfccbd45d1f2538097d5a031fa68bbb43c84d12b3de47b7061c0d5e24993e0c87
alphaP:

During processing a message `u_1`, calculation the `K_B` key and the message `u_2` on the subject B the parameters `betta`, `src`, `K_B` = HASH (`src`), `betta*P` and `u_2` take the following values:

```
betta=0x0d494d54fb777781d1324ed6088bb0d9d86b8b0a252aa6a3ee70af8ef44b87a6
4cea3a432b61a699bad2d9760d700c2891b6285be0b0bb90f16a40a9b2e0e36a
```

`src`:

```
c2 a3 1a 15 08 52 8a fb 70 be d5 7a 3a 97 9a 3a
8c ed 00 2f 1b 05 8f 99 cb ee 64 56 5c cb ae 42
c5 80 b1 39 18 04 b3 e3 34 d0 2f 70 55 18 ef 16

```

During processing a message `u_2` and calculation the key on the subject A the `K_A` key takes the following value:

`K_A`:

```
84 14 e1 12 6c 56 a1 1e 1f 5e a0 b7 c3 bd ab e9
8b 26 8b 59 d4 08 f9 7c d0 ea d7 c2 7e e4 9c 15
```

The message `MAC_A`=HMAC (`K_A`, `0x01 || ID_A || ind || salt || u_1 || u_2`) from the subject A takes the following value:

`MAC_A`:

```
53 0b 77 63 c5 9e 7c 98 52 59 ad eb af a4 16 41
c6 f4 35 47 85 01 bd c9 7e a9 cf 88 a6 9a 12 8c
```

The message `MAC_B`=HMAC (`K_B`, `0x02 || ID_B || ind || salt || u_1 || u_2`) from the subject B takes the following value:

`MAC_B`:

```
3f 48 65 b8 8c 81 e5 ac 56 1e 31 c1 b3 d1 d9 0c
57 e1 e7 4b ac 77 b1 63 ac 60 74 82 4e 99 d3 cc
```
